## ACKNOWLEDGEMENT

It is with great pride that we express our gratitude in-depth to our institution “**EXCEL ENGINEERING COLLEGE**” for providing us the opportunity to do the Design Project.

We are greatly indebted to our Honorable Chairman **Dr. A.K. NATESAN, M.Com., MBA (NIT), M.Phil., Ph.D., FTA**, for providing all the necessary facilities for successful completion for the Design Project.

We Express our heartiest gratitude and thanks to our respected Vice Chairman **Dr. N. MATHAN KARTHICK, M.B.B.S., MISTE., PHIE.**, of **EXCEL GROUP OF INSTITUTIONS** for providing all the facilities for successfully completing the Design Project.

We like to place on record to our beloved Principal and Executive Director **Dr. K. BOMMANNA RAJA, M.E., Ph.D.**, for his valuable suggestion in our entire endeavour.

We thank the Head of the Department **Prof. P. JAYAPRABHA, M.E.**, of Artificial Intelligence and Data Science for her guidance, constant inspiration and encouragement.

We wish to express our Heartfelt Thanks and sincere acknowledgment to our respected **Mrs. S.L. SWARNA, M.TECH**, for her encouragement and dedicated guidance.

We take the privilege to record our everlasting and loving thanks to our parents for their kind help and support which render in bringing our Project full manner.

## **ABSTRACT**

The Virtual Object Dimension Measurement System is a cutting-edge technological solution designed to revolutionize the way we measure and analyse the dimensions of objects in a virtual environment. This innovative project harnesses the power of computer vision, augmented reality, and machine learning to provide precise and efficient measurements of real-world objects. The primary objective of this project is to create a system that can detect objects and accurately measure the dimensions of objects in a virtual space, allowing computer model to obtain critical information about the size, shape, and spatial relationships of objects.

# **CHAPTER 1**

## **INTRODUCTION**

The Virtual Object Dimension Measurement system in an increasingly digital and interconnected world, the need for precise and efficient measurement of physical objects is paramount. Whether in fields like architecture, engineering, manufacturing, or everyday tasks like home improvement, accurate dimensions are crucial. The Virtual Object Dimension Measurement System project emerges as a groundbreaking solution at the intersection of technology and measurement, offering an innovative way to bridge the gap between the physical and digital realms.

Traditionally, measuring the dimensions of real-world objects has relied on physical tools such as rulers, tape measures, and calipers, often demanding a physical presence and time-consuming manual processes but at other side while the computer model or autonomous system have to know the dimension of object which are virtually present in image , it is critical to know about the dimesion of virtual object to a automatic system or robot . The Virtual Object Dimension Measurement System seeks to revolutionize this paradigm by leveraging cutting-edge technologies, including computer vision, augmented reality, and machine learning, to provide accurate and efficient measurements of objects in a virtual environment.

This project's primary goal is to create a seamless and user-friendly system that empowers individuals, professionals, and industries to obtain precise measurements without the need for physical contact with the objects being measured. By harnessing the capabilities of augmented reality, the system overlays virtual measurement markers on real-world objects in real time, providing users with an immersive and interactive measuring experience.

### Key Points of the Virtual Object Dimension Measurement System:-

1. **Computer Vision and Augmented Reality:** The project relies on computer vision techniques to recognize and locate physical objects within the user's environment. Augmented reality then superimposes digital measurement tools on these objects, enabling users to measure dimensions and distances with unprecedented ease and accuracy.
2. **User-Friendly Interface:** Accessibility is a core focus of this system. It offers an intuitive interface through smartphones, smart glasses, or other AR-enabled devices, ensuring that users of varying backgrounds and expertise can interact with the technology effortlessly.
3. **Precise and Accurate Measurements:** The project integrates advanced algorithms and machine learning models to guarantee highly accurate measurements. Users can confidently measure dimensions of various element present in one image (it can be also improved for real time scenario).
4. **Scalability:** The Virtual Object Dimension Measurement System is designed to cater to a wide range of applications. It can be used for home improvement projects, architectural designs, engineering tasks, quality control in manufacturing, and various other scenarios, offering a versatile and adaptable solution.
5. **Data Visualization and Export:** Users can visualize and record measurement data in different formats, and the system provides the option to export results for further analysis or integration with other software tools.

## **1.1 Scope of project**

The scope of the Virtual Object Dimension Measurement System project is comprehensive and encompasses various domains and applications. This innovative system aims to bridge the gap between the physical world and the digital realm, offering precise and efficient measurement capabilities. The project's scope includes, but is not limited to, the following aspects:-

Architecture and Engineering, Construction, Interior Design and Home Improvement, Manufacturing and Quality Control, Healthcare, Education and Training, Art and Design...etc.

## **1.2 Objective of the Project**

The Primary objective of “Virtual Object Dimension Measurement Object” to detect the object in image and measure the size or dimension of the various object . This is mainly developed for virtual world where the computer model have to know about the dimension of objects present in image or it can be also built for real time scenario.

## **CHAPTER 2**

### **LITERATURE SURVEY**

#### **2.1 Computer Vision and Augmented Reality**

Literature in computer vision and augmented reality provides the foundational concepts and technologies required for object recognition and overlaying virtual measurements onto physical objects. Nadim Mahmud, Jonah Cohen, Kleovoulos Tsourides, Tyler M. Berzin. Gastroenterology Report, Volume 3, Issue 3, August 2015, Pages 179–184

#### **2.2 Augmented Reality Measurement Apps**

Research on augmented reality measurement apps for smartphones and smart glasses offers insights into existing applications that provide measurements using augmented reality.

#### **2.3 Machine Learning and Object Recognition**

Machine learning algorithms for object recognition and feature extraction are crucial for accurate measurements. Studies on object detection and pose estimation are pertinent. It's invented Y. KODRATOFF and S. MOSCATELLI.

#### **2.4 3D Scanning and Modelling**

Research on 3D scanning technologies and software tools for creating virtual models of physical objects is relevant for understanding the digitization process. Ertu Unver, Atkinson Paul & Tancock Dave , Pages 41-48 , Published on 05 Aug 2013.

**2.5 Human-Computer Interaction (HCI) :** HCI research that explores user interfaces and user experience design in augmented reality and virtual environments is essential for creating an intuitive system.

## **2.6 Spatial Computing and Mixed Reality**

Literature on spatial computing and mixed reality provides insights into the seamless integration of physical and digital environments for measurement.

## **2.7 Applications in Architecture and Engineering**

Case studies and research on the use of augmented reality and virtual measurement in architectural and engineering projects offer practical insights. Hung-Lin Chi , Shih-Chung Kang , Xiangyu Wang , Accepted 29 December 2012, Available online 22 January 2013.

## **2.8 Quality Control in Manufacturing**

Studies on the application of augmented reality and computer vision in manufacturing processes for quality control and measurements.

## **2.9 Medical Augmented Reality**

Research on medical applications of augmented reality, including surgical guidance and anatomical measurements, is relevant.

## **2.10 Educational Technology**

Literature on the integration of augmented reality and virtual measurement tools in educational settings for STEM (Science, Technology, Engineering, and Mathematics) subjects.

## **2.11 Art and Design Tools**

Studies on tools and technologies used by artists, designers, and sculptors that incorporate augmented reality and virtual measurements.

## **2.12 Data Visualization and Export**

Research on data visualization techniques and methods for exporting measurement data for further analysis.

### **2.13 Accessibility Technologies**

Studies on technologies designed to improve accessibility for individuals with disabilities, particularly in measurement and spatial understanding.

### **2.14 Inventory Management and Logistics**

Research on using augmented reality for inventory management and logistics, including case studies on warehouse applications.

### **2.15 Remote Collaboration and Communication**

Literature on technologies that facilitate remote collaboration and communication, especially in the context of augmented reality and measurements.

### **2.16 Security and Privacy in AR**

Understanding the challenges and solutions related to security and privacy when using augmented reality in measurement applications.

### **2.17 Challenges and Future Directions**

Reviewing the current challenges in virtual object dimension measurement and identifying potential research directions for further improvement.

### **2.18 Calculating the Width of the object**

Camval is referred as the height from camera to image while capturing the picture and x is referred as the width parameter of an object (pixels). The x value indicates the operation given in the equ(1). By analysis of data, y and z values depends on the ratio camval parameter to the object's physical width. y value can be acquired from the equ(2), z value can be acquired from an equ(3).

$$X=y*K+z \quad (1)$$

$$Y=m1* \frac{\text{camval}}{\text{width}} -b1 \quad (2)$$

$$z = m_2 * \frac{\text{camval}}{\text{widRc al} - b} \quad (3)$$

For finding the estimated width value we have to find the values of the equ((1),(2),(3)). P is referred as the estimated width.

$$P = \text{camval} * \frac{x + b_1 * K + b_2}{m_1 * K + m_2} \quad (4)$$

## 2.19 Calculating the Height of the object

Suppose consider a reference model camval value is as same as a theoretical model having the same height. Q is referred as the reference model and indicates the equ(5).

$$Q = m_1 * K + m_2 * \text{camval} + b_2 \quad (5)$$

Herethe height parameter of the reference model can be obtained from equ(5) and indicated by Q. where K is the parameter for values of distance in pixels of the lower border of displayed area and displayed object, camval is parameter that can be obtained from equ(1) and  $b_2 = 203.7$ ,  $m_2 = 0.06892$ ,  $m_1 = -1.028$  are the constant values that are acquired from the data analysis.

M is referred as the the original height of the calculated object. The main goal is to acquire an estimated height parameter as equally close to the M value. Distance between real0 and real2 is referred as reference model's physical height. The distance is the cam value, i.e., equal as the height parameter of the camera. M is the parameter value indicates original object's displayed height(pixels) and N refers to reference model's displayed height. In case of Logitech C920 HD Pro Webcam camera, gamma value is the twice the value of vertical angle of view. The aim is to find estimated height value from the equ(6), that will be possibly equal to M value. Camvalvalue is the height from camera to picture while capturing the pictures, with possible values of K coefficient is -1 or 1. If Q, is greater than the pixHeig, then K value is -1, otherwise K value is 1. Based on basic fundamental trigonometry rules, one can find the value of distance between real1 and real2 from the equ(6) using basic trigonometry rules. The p

value can be to obtain from equ(7).  $y$  value is the subtraction between angles values  $\gamma$  and  $\delta$ , equ(8).  $\delta$  value is possible to obtain from equ(9).

$$\text{estHeig} = \text{camval} + k * \tan(p) * D \quad (6)$$

$$p = \frac{\text{pixHeig} - Q}{Q} * y \quad (7)$$

$$y = \gamma - \delta \quad (8)$$

$$\delta = \frac{K}{K + N} * \gamma \quad (9)$$

$D$  is referred as the camera's horizontal distance and the computed object, that is possible to obtain from the equ(10). The equ(10) uses the  $\alpha$  values acquired from previously used equations.

$$D = \cot(y) * \text{camval} \quad (10)$$

## 2.20 The filtering of shadows and background

The object detection system provides two different options for background and shadow filtering of the object. The primary option is finding the object measurements using RGB model; this solution from the object will be calculated with its shadow. The another option is to remove the shadows formed from the object. The CIE Lab was selected for this work, after so many tests of different color models. By using the CIE Lab color model, it was found that it reduces the shadows formed by the objects in the photo. If the object is white, or in a shades of grey, or black, the CIE Lab model usage will be a drawback.

**Fig. 2.19 Sample Picture**

If the picture of an object is clicked in a situation where the shadows of the object will not affect the edge recognition in an object, so, the measurement of an object can be done without the need of shadows filtering. The detection is difficult when the object has a several areas with significantly various colors. In that type of cases, only any one of the areas with color is detected as the object.

## **CHAPTER 3**

### **EXISTING SYSTEM**

There are various system are available for object size measurement , that are use for realtime physical object size measurement. Some are :-

#### **3.1 Augmented Reality (AR) Measurement Apps**

Various mobile apps and software, such as AR Ruler, AR Measure, and ARKit/ARCore-based apps, leverage smartphone cameras and AR technology to measure distance and dimensions of real-world objects.

#### **3.2 Laser Scanning and LiDAR**

Laser scanning and LiDAR (Light Detection and Ranging) systems are used for 3D scanning and precise measurements in fields like surveying, construction, and archaeology. Teemu Hakala, Juha Suomalainen, Sanna Kaasalainen, and Yuwei Chen , 26 March , 2012 | PP. 6851-8218.

#### **3.3 3D Scanning and Modeling Software**

Software tools like Autodesk ReCap and Trimble RealWorks enable the creation of 3D models from scanned objects, which can be used for dimensional analysis.

#### **3.4 Smart Glasses and Head-Mounted Displays (HMDs)**

Devices like Microsoft HoloLens and Google Glass offer augmented reality capabilities, allowing users to view virtual measurements in their field of vision. Fabien Lareyre, Arindam Chaudhuri, August 2021, Pages 497-512.

#### **3.5 Industrial Measurement Systems**

Industries like manufacturing and quality control use specialized measurement systems that incorporate vision technology and sensors for precise measurements.

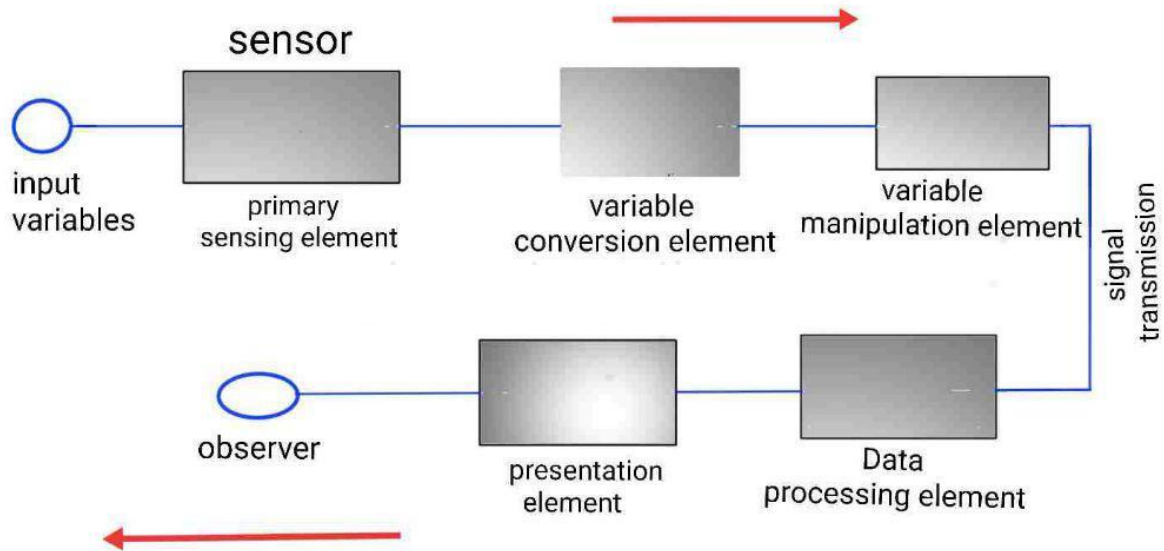

Fig. 3.5 : Industrial Measurement Systems diagram

### 3.6 Gaming and Entertainment

Virtual reality (VR) and augmented reality are utilized in gaming and entertainment for interactive experiences, offering insights into immersive digital interactions with objects. Eugene Martin Christiansen, Julie Brinkerhoff-Jacobs, April 1995, Pages 6, 79-94.

### 3.7 Remote Collaboration Tools

Collaboration platforms like Microsoft Teams and Zoom incorporate AR features that enable remote participants to share and interact with virtual content. Gheorghe H. Popescu, Florin Cristian Ciurlău, Cristian Ionuț Stan, Cecilia Băcănoiu (Văduva), Alina Tănase (Veisa), October 2022, page range : 21-34.

## CHAPTER 4

### PROPOSED WORK

#### 4.1 Introduction

In this paper, we propose an approach that uses the video or image of the surroundings captured by the computer's webcam or external camera as an input to identify items, measure their dimensions, and identify them. With a stand, we are able to keep the camera at a specific distance while also adjusting the camera's height, width, and depth. With the use of this system, we are able to identify many objects at once, provide their dimensional measurements, and obtain other information such as the object's area of occupancy. The system is created using a python program which makes use of python libraries for queue, math, numpy, and computer vision (opencv-cv2). This system is composed of three modules(a,b and c) that act in accordance with various system-related tasks and are discussed below sequentially.

**Module a** - the first module is used for obtaining the video frames input, in this module we configure our environment by setting the camera width, height and also we set the frame rate of the video input.

**Module b** - the second module is used to detect object by capturing the objects boundaries. There are multiple functions performed in this module. Initially the input frame to gray scale to get better understanding of the details in input. Then we apply Gaussian blurring this methodology substitutes a Gaussian kernel for a box filter. The cv.GaussianBlur() function has completed its work. The kernel's width and height should be positive and odd, accordingly. Furthermore, we must supply sigmaX and sigmaY, which stand for the standard deviations in the X and Y axes, respectively. sigmaY is assumed to be the same as sigmaX if only sigmaX is supplied. If either or both are provided as zeros, values are chosen based on the kernel size. In order to exclude Gaussian noise from an image, Gaussian blurring

is highly effective. Then image thresholding `cv.threshold()` is applied, the thresholding is achieved through using procedure `cv.threshold`. The provided image, which must be in grayscale, is the first argument. The threshold value, which is used to classify the pixel values, is the second input. The following input determines the highest value that will be given to pixel values that are higher than the threshold. The function's final parameter, which is obtained using OpenCV, supports multiple types of thresholding. Then contours are detected three choices exist when employing the `cv.findContours()` function: source picture, contour retrieval mode, and contour approximation method. And the hierarchy and contours are produced. List of every contour in the image is identified as contours. The (x,y) coordinates of an object's border points are arrayed for each contour.

**Module c** - the third module is used to find the object dimensions by using the contour data we find the various lengths of the object from the math library we use `hypot` method which is used to calculate euclidean distance, there by allowing us to calculate length, breadth, and also also area of the object.

web sources, and for other things. We will send the request and through the API we will get the corresponding output.

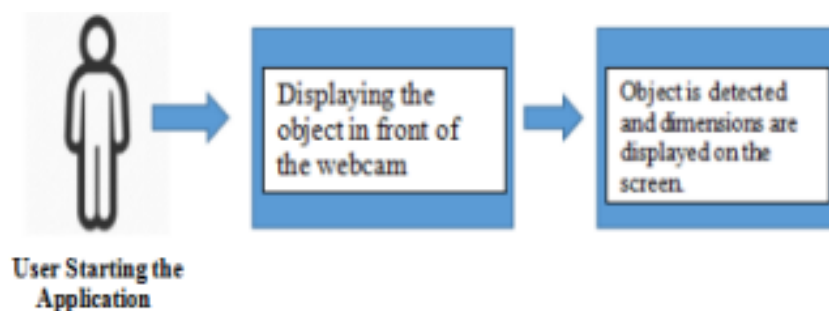

Fig. 4.1 : Block diagram of proposed approach

## 4.2 System Architecture Design

Define the overall architecture of the system, including the integration of computer vision, augmented reality, Machine learning, and data processing components.

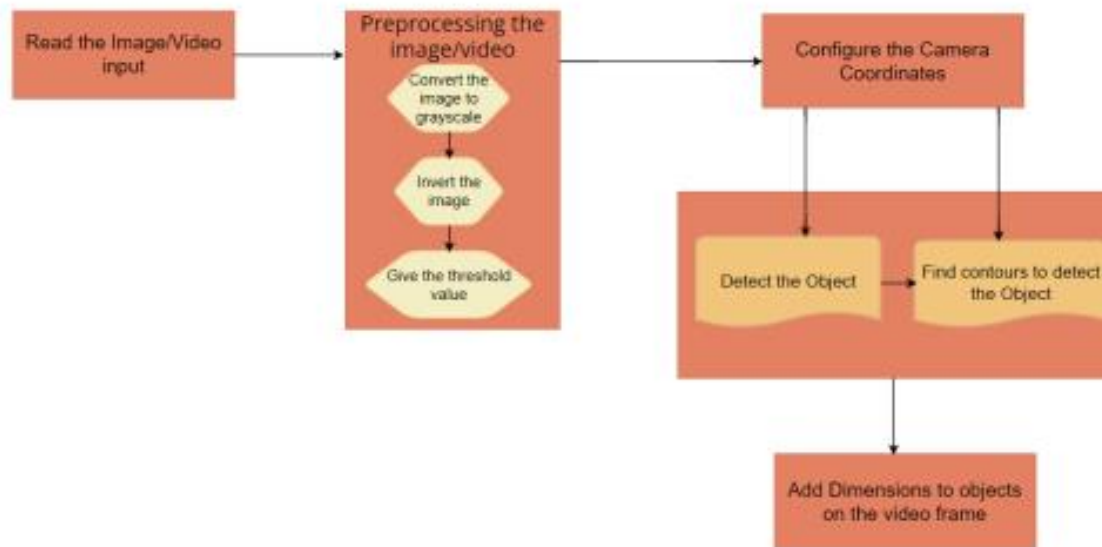

Fig. 4.2 : System Architecture Design

## 4.3 Object Recognition and Tracking

Develop algorithms for object recognition and tracking using computer vision to identify and locate physical objects within the user's environment.

## 4.4 Object detection and identification from stereo images

The proposed measurement system consists of object detection on the stereo images and blob extraction and distance and size calculation and object identification. The system also employs a fast algorithm so that the measurement can be done in real-time. The object measurement using stereo camera is better than object detection using a single camera that was proposed in many previous research works. It is much easier to calibrate and can produce a more result.

Fig. 4.4 : Object detection and identification from stereo images

#### 4.5 Stereo Object Size and Distance Measurement

The flow of the object size measurement system that we proposed started with stereo vision image capture. Then, on both images, a pre-processing will be applied followed by object detection and segmentation. Finally, the object distance and size will be calculated. From the object size, object identification can be done.

| Measured Distance (m) | Actual Distance (m) | Error (m) |
|-----------------------|---------------------|-----------|
| 3.101                 | 3.000               | -0.101    |
| 3.088                 |                     | -0.088    |
| 2.901                 |                     | 0.099     |
| 3.112                 |                     | -0.112    |
| 5.203                 | 5.000               | -0.203    |
| 4.880                 |                     | 0.120     |
| 5.204                 |                     | -0.204    |
| 5.199                 |                     | -0.199    |
| 7.016                 | 7.000               | -0.016    |
| 6.880                 |                     | 0.120     |
| 7.250                 |                     | -0.250    |
| 6.810                 |                     | 0.190     |
| 9.917                 | 10.000              | 0.083     |
| 9.780                 |                     | 0.220     |
| 10.211                |                     | -0.211    |
| 10.180                |                     | -0.180    |

Table 1 : Object Distance Measurement Result

## 4.6 Stereo Image Capture

Stereo image capture is done by using two video cameras which are aligned in parallel in fixed position. Both cameras are calibrated so that have matching image properties such as the size , colour space and lighting and corrected from distortion. The object of interest can be measured for its distance and size when it enters the overlapping view of the two cameras.

## 4.7 Pre-Processing

After the images are captured, the size of the image is down-scaled to quarter of its original size to improve the computation speed. For the proposed system , the original size which is 1280x720 pixels is downscaled to 640x360 pixels. This reduction of size does not affect the accuracy of the system since the size of the object of interest in original image is bigger than 2x2 pixels.

The downscaling applied earlier help to reduce the noise in the image since it averages a group of pixels together which inherently produce a smoothing effect. We further remove the souse by applying a median filtering on the images. Median filter is selected since it is fast and able to produce sufficient smoothing.

| Object       | Measured Width (cm) | Actual Width (cm) | Error (cm) |
|--------------|---------------------|-------------------|------------|
| Chair        | 52.065              | 51.000            | -1.065     |
|              | 52.970              |                   | -2.970     |
|              | 49.830              |                   | 1.170      |
|              | 49.571              |                   | 1.429      |
| Beverage Box | 9.612               | 9.000             | -0.612     |
|              | 10.510              |                   | -1.510     |
|              | 7.786               |                   | 1.214      |
|              | 8.901               |                   | 0.099      |
| Table        | 67.860              | 68.000            | 0.140      |
|              | 69.015              |                   | -1.015     |
|              | 69.652              |                   | -1.652     |
|              | 66.083              |                   | 1.917      |
| Pencil Box   | 31.250              | 30.000            | -1.250     |
|              | 32.208              |                   | -2.208     |
|              | 28.786              |                   | 1.214      |
|              | 29.550              |                   | 0.450      |

Table 2 : Object width measurement results

## 4.8 Object Detection

Different most of the other stereo vision works the stereo matching process that we utilizes is only applied to the object of interest which can be detected using an object detection algorithm. This approach is much faster compared to the stereo matching using features similarity in the two images. In our proposed system, the object of interest is basically a foreign moving object that enters the view of the stereo vision system. We assume that the cameras of the system are always fixed to one position. Hence, the detection of the object of interest is done using two operations, the pixel to pixel background subtraction and thresholding.

The background subtraction is done by taking the difference of every pixel,  $I_r$  in the image to its respective reference pixels in the background model,  $I_{BG}$ . The difference value is then thresholded with a value,  $TR$  to determine if the pixel belongs to the object of interest or not. If the pixel does not belong to the object of interest, it will be used to update the background model.

$$IT = \text{object if, } |IT - IBG| > TR$$

Background model is initialized by assuming that the first frame in the video is the background. The background model is updated by averaging the new intensity with the background model intensity value. An on-line cumulative average is computed to be a new background as:

$$\mu_T = \alpha I + (1 - \alpha) \mu_{T-1}$$

where  $T$  is the model intensity,  $I$  is the intensity and  $\alpha$  is update weight. The value for  $\alpha$  is set to be 0.5.

## 4.9 Object Segmentation

The binary image resulting from the background subtraction and thresholding stage is then processed for object of interest segmentation. Firstly, a quick morphology is applied on the binary image to improve the subtraction

result. A sequence of erode and dilate operation are involve in the morphology where the effect is to remove smaller detected regions usually due to noise and to enlarge the areas of object of interests and to close any holes within them We then applied a connected component analysis on the image to segment the object of interests on the image. Connected component analysis locates separated regions in the binary image and labels them as different objects. A one pass connected component analysis is applied to improve the speed of the system. From the connected component analysis results, blob extraction is done by drawing the bounding box around every object of interests.

Fig. 4.9 : Object detection and recognition processing

#### 4.10 Object Distance and Size Measurement

Up to this point, all the processing was done in parallel on two images captured from the two cameras. Distance measurement and size calculation use

the 1375 information extracted from the object of interest information on both images.

Distance measurement is done by using the using the disparity value of the object of interest in the two image,  $d$  in pixel. Since the camera is aligned in parallel, we can simply take the pixel difference between the two width centre lines of the object of interest as the disparity.

The distance,  $D$  of the object can be calculated using the following equation:

$$D = \beta d^{-1} \quad \text{where } \beta = b f$$

where  $b$  is the separation distance between two cameras and  $f$  is focal length of the cameras.

For size measurement, which consists of width and height, the calculations are done by using the disparity value in pixel,  $d$  and the pixel value of the width,  $w$  and the height,  $h$  of the blob. The calculations of actual object width,  $W$  and height,  $H$  are done using the relationship of between width per pixel, and height per pixel,  $\lambda$  to the disparity. From our experiment we found that width per pixel and the height per pixel value of an object are linear and inversely proportional to its disparity. The equation for the width,  $W$  and height,  $H$  calculation is as the following:

$$W = \lambda_w w \quad H = \lambda_h h$$

$\lambda_w$  and  $\lambda_h$  are obtained from a linear equation of a graph of  $\lambda_w$  and  $\lambda_h$  against  $d$  as the following:

where  $m$  is the gradient of the plotted graph and  $c$  is the value of  $\lambda$  at  $d = 0$ .

The graphs of  $\lambda_w$  and  $\lambda_h$  against  $d$  are plotted by experimenting on several samples with known actual width and height. Different disparity value is obtained by varying the distance of the object from the camera.

| Object       | Measured Height (cm) | Actual Height (cm) | Error (cm) |
|--------------|----------------------|--------------------|------------|
| Chair        | 80.784               | 80.600             | -0.184     |
|              | 78.645               |                    | 1.955      |
|              | 79.901               |                    | 0.699      |
|              | 82.020               |                    | -1.420     |
| Beverage Box | 20.196               | 19.000             | -1.196     |
|              | 19.780               |                    | -0.780     |
|              | 17.661               |                    | 1.339      |
|              | 19.518               |                    | -0.518     |
| Table        | 77.440               | 78.000             | 0.560      |
|              | 77.480               |                    | 0.520      |
|              | 76.298               |                    | 1.702      |
|              | 79.519               |                    | -1.519     |
| Pencil Box   | 5.852                | 5.000              | -0.852     |
|              | 5.198                |                    | -0.198     |
|              | 3.986                |                    | 1.014      |
|              | 4.101                |                    | 0.899      |

Table 3 : Object height measurement results

#### 4.11 Object Identification

Different objects can be distinguished from each other depending on their sizes. For example, a car will have a different width compared to a pedestrian. For our system object is identified according to their height,  $h$  to width,  $w$  ratio and the height-width,  $hw$  product (blob area).

A database is utilized to store the information and the associated label of known objects. If an object with matching information is found, the object will be identified. When a new object with no matching height to width ratio and height-width product is found, a new label will be instantiated for that object in the database.

Fig. 4.11 : object detection and measurement of size

#### 4.12 System Flow Diagram

## CHAPTER 5

### SYSTEM SPECIFICATION

#### 5.1 Hardware Requirement

- **Camera:** The system should support one or more high-resolution cameras with the capability to capture clear images and videos of objects.
- **Processing Unit:** A powerful processor is required to handle image processing, object recognition, and measurement calculations efficiently.
- **Memory:** Sufficient RAM and storage space for storing captured data, processing images, and running the application smoothly.
- **Display:** A high-quality display is necessary for presenting measurement data, visual cues, and augmented reality overlays.
- **Sensors:** Depending on the application, additional sensors such as LiDAR, depth sensors, or accelerometers may be required to improve measurements and object recognition.

#### 5.2 Software Requirements

- **Operating System:** Specify the compatible operating systems for the application, which might include Android, iOS, Windows, or others.
- **Computer Vision and Machine Learning Libraries:** Utilize computer vision and machine learning libraries such as OpenCV, TensorFlow, or PyTorch to implement object recognition and measurement algorithms.
- **Augmented Reality Framework:** Utilize AR frameworks like ARKit, ARCore, or other open-source alternatives to create the augmented reality user interface.

- **Measurement Algorithms:** Develop algorithms for measuring dimensions, distances, angles, and other parameters based on recognized objects. These algorithms should be highly accurate.
- **User Interface (UI):** Design an intuitive and user-friendly UI for easy interaction, object selection, and measurement visualization.

### 5.3 Functional Specifications

- **Object Recognition:** Specify the accuracy and speed of the object recognition process, including the types of objects that can be recognized.
- **Measurement Accuracy:** Define the level of measurement accuracy and precision the system is designed to achieve for different types of objects.
- **Augmented Reality Features:** Describe the augmented reality features, including the overlay of measurement markers, annotation tools, and interactive elements.
- **Data Export:** Specify the formats for exporting measurement data, including options for sharing or saving measurements.

### 5.4 Performance Requirements

- **Frame Rate:** Define the minimum acceptable frame rate for real-time object recognition and augmented reality overlays.
- **Latency:** Specify the maximum acceptable latency between object recognition and measurement display.
- **Scalability:** Ensure the system can handle a wide range of object sizes, from small objects to large structures.

## 5.5 Security and Privacy

- **User Data Protection:** Specify measures to protect user data, including images and measurements, and ensure compliance with privacy regulations.

## 5.6 Accessibility and Inclusivity

- **Accessibility Features:** Describe features that make the system accessible to individuals with disabilities, such as voice commands or screen reader support.

## 5.7 Testing and Validation

- **Testing Scenarios:** Define the testing scenarios, including controlled environments and real-world scenarios, to validate the system's accuracy and performance.

## 5.8 Documentation and User Support

- **User Manuals:** Provide comprehensive user documentation that explains how to use the system effectively.
- **User Support:** Describe the resources available for users to seek assistance and troubleshoot issues.

## 5.9 Customization and Integration

- **Customization Options:** Specify how the system can be customized to meet the specific needs of different industries or applications.
- **Integration with Other Systems:** Describe any available APIs or integration capabilities to link the system with other software or hardware.

## 5.10 Future Enhancements

- **Roadmap:** Outline potential future enhancements and features that can be added to the system in subsequent updates.

## **CHAPTER 6**

### **IMPLEMENTATION AND RESULTS**

#### **6.1 Setup of proposed system**

We proposed the system to measure objects in a real time video and pictures. We prepared a few experimental setups to test the correctness of the proposed method. The implement the proposed system has made by the help of Python language. Figure 6. show that the setup of the prepared system. Except the hardware formation, the software's required has installed.

Fig. 6.1 : Setup of proposed system

#### **6.2 Display output on the screen**

For the experiment the camera has been effectively. capturing the pictures. The proposed system applies four operations such as record frames, find edges, find objects, and measure size for each object. When we run the application. the output screen displays on the PC screen as appear in below Figure.

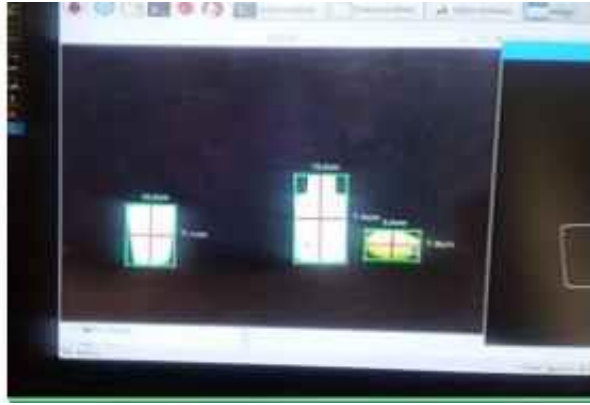

Fig. 6.2: Display output on the screen

### 6.3 Calculate the size of objects

In below Fig. illustrates the object detection and measurements. The size of each object in the frame which are calculated.

Fig. 6.3 : Calculate the size of objects

In the first experiment we measured size of objects such as white glasses, orange cup, bottle, potatoes. Table I, shows the accuracy of proposed object measurement system for these objects. Abbreviations in the table are as follows; AM-H: Actual Measure-Height, PM-H: Proposed Measure-Height, AM-W: Actual Measure-Width, PM-W: Proposed Measure- Width.

| Name of objects | AM-H (cm) | PM-H (cm) | AM-W (cm) | PM-W (cm) | Accuracy (%)   |
|-----------------|-----------|-----------|-----------|-----------|----------------|
| White glasses   | 10.0      | 10.5      | 6.8       | 7.1       | % 95.45        |
| Orange cup      | 8.5       | 9.0       | 7.5       | 7.4       | % 97.56        |

Table 4 : Accuracy object measurement for one frame

#### 6.4 Experimental result when camera above the objects

Nevertheless, not every result are perfect, since this is due to the seeing angle and lens deformation. By calibrate the camera and set good width parameter, accuracy will be increase.

In the second experiment, we set the camera above the objects. Figure 6.4 , shows that the results of the object detection and measurement for another objects. And the Table 6.4. demonstrations the accuracy values among actual measure and system measure.

Fig. 6.4 : Experimental result when camera above the objects

| Name of objects | AM-H (cm) | PM-H (cm) | AM-W (cm) | PM-W (cm) | Accuracy (%)  |

Table 5 : Accuracy object measurement when camera above the objects

The result for error column displays very low errors. The error rate is especially smaller when camera above the objects.

## **CHAPTER 7**

### **CONCLUSION**

In this project, a method for finding the object measurements present in an images using a camera was explained and related execution of software is explained. The identification of an object is based on taking two images in the same scenario without and with the object present in an image. The identified objects is distinguished by the size of object area displayed and the co-ordinates. The output obtained from these images are taken as input data for the equations to calculate the size. Based on the tests conducted, by considering various heights and distances of an object, and using various objects, it was found that the deviation of the measurement from original measurement is less than 7-10%.
